DATA

General:
Spectral Response.......................... S-4
Wavelength of Maximum Response.......... 4000 ± 500 angstroms
Cathode:
  Minimum Projected Length*.............. 15/16"
  Minimum Projected Width*............... 5/16"
Direct Inter-electrode Capacitances:
  Anode to Dynode No. 9................... 4 µf
  Anode to All Other Electrodes.......... 6.5 µf
Maximum Overall Length.................... 3-11/16"
Maximum Seated Length...................... 3-1/8"
Length, Base Seat to Center of
  Useful Cathode Area..................... 1-15/16" ± 3/32"
Maximum Diameter......................... 1-5/16"
Bulb........................................ T-9
Mounting Position........................ Any
Base........................................ Small-Shell Submagnal 11-Pin,
  Non-Hydroscopic
Easing Designation for BOTTOM VIEW...... 11K

Pin 1 - Dynode No.1
Pin 2 - Dynode No.2
Pin 3 - Dynode No.3
Pin 4 - Dynode No.4
Pin 5 - Dynode No.5
Pin 6 - Dynode No.6

Direction of Light

Maximum Ratings, Absolute Values:
ANODE-SUPPLY VOLTAGE (DC or Peak AC)*...... 1250 max. volts
SUPPLY VOLTAGE BETWEEN DYNODE No. 9
and ANODE (DC or Peak AC).............. 250 max. volts
PEAK ANODE CURRENT...................... 10 max. ma
AVERAGE ANODE CURRENT*................ 1 max. ma
AMBIENT TEMPERATURE...................... 75 max. °C

Characteristics:
With 100 volts per dynode stage and
100 volts between dynode No. 9 and anode

§ For conditions the same as shown under Anode Luminous Sensitivity except that the value of light flux is 0.01 lumen and that 100 volts are applied between cathode and all other electrodes connected together as anode.

* Measured under conditions specified on sheet "PHOTOTUBE SENSITIVITY AND SENSITIVITY MEASUREMENTS" at the front of this Section.

* Ratio of anode sensitivity to cathode sensitivity.

* Defined as the value where the rms output current is equal to the rms noise current determined under the following conditions: 100 volts per stage, 25°C tube temperature, ac-amplifier bandwidth of 1 cycle per second, tungsten light source at 2870K interrupted at a low audio frequency to produce incident radiation pulses alternating between zero and the value stated. The “on” period of the pulse is equal to the “off” period. The output current is measured through a filter which passes only the fundamental frequency of the pulses.

---

SPECTRAL-SENSITIVITY CHARACTERISTIC of Phototube having S-4 Response is shown at the front of this Section.

---

OPERATING NOTES

The operating stability of the 931-A is dependent on the magnitude of the anode current and its duration. When the 931-A is operated at high values of anode current, a drop in sensitivity (sometimes called fatigue) may be expected. The extent of the drop below the tabulated sensitivity values depends on the severity of the operating conditions. After a period of idleness, the 931-A usually recovers a substantial percentage of such loss in sensitivity.

(continued on next page)
The use of an average anode current well below the maximum rated value of 1.0 milliampere is recommended when stability of operation is important. When maximum stability is required, the anode current should not exceed 250 microamperes.

© OF BULB WILL NOT DEVIATE MORE THAN 2° IN ANY DIRECTION FROM THE PERPENDICULAR ERECTED AT CENTER OF BOTTOM OF BASE.

Indicates a change or addition.
Tube operation at room temperature or below is recommended.

This value is calculated from the typical anode luminous sensitivity rating using a conversion factor of 1036 lumens per watt.

Under the following conditions: The light source is a tungsten-filament lamp having a lime-glass envelope. It is operated at a color temperature of 2870° K and a light input of 10 microlumens is used.

This value is calculated from the typical cathode luminous sensitivity rating using a conversion factor of 1036 lumens per watt.

Under the following conditions: The light source is a tungsten-filament lamp having a lime-glass envelope. It is operated at a color temperature of 2870° K. The value of light flux is 0.01 lumen and 100 volts are applied between cathode and all other electrodes connected as anode.

At a tube temperature of 22° C. With supply voltage adjusted to give a luminous sensitivity of 20 amperes per lumen. Dark current caused by thermionic emission may be reduced by use of a refrigerant.

At 4000 angstroms. These values are calculated from the EADCI values in lumens using a conversion factor of 1036 lumens per watt.

Under the following conditions: Tube temperature 22° C, external shield connected to cathode, bandwidth 1 Hz, tungsten-light source at a color temperature of 2870° K interrupted at a low audio frequency to produce incident radiation pulses alternating between zero and the value stated. The "on" period of the pulse is equal to the "off" period.

At 4000 angstroms. This value is calculated from the ENI value in lumens using a conversion factor of 1036 lumens per watt.

Measured between 10 per cent and 90 per cent of maximum anode-pulse height. This anode-pulse rise time is primarily a function of transit time variation and is measured under conditions with the incident light fully illuminating the photocathode.
The electron transit time is the time interval between the arrival of a delta function light pulse at the entrance window of the tube and the time at which the output pulse at the anode terminal reaches peak amplitude. The transit time is measured under conditions with the incident light fully illuminating the photocathode.
